### HINTS AND TIPS

Always check the obvious before removing components. For example: Is the Power Supply Unit OK? Is the Disk Drive Unit functioning correctly? Are all leads securely attached? Is the Monitor OK?

Most faults causing the computer not to initialize will be found on one of the custom chips or the CPU or possibly more than one memory chip is down.

Disk drive faults will be located on the drive or one or both of the CIAs, usually.

certain areas of the computer. This will assist your further in the use of the quide. The third section contains all the data charts for each I.C. in the computer and the signals that should be present on each pin. Within this section are details of the Address and Data lines and Video and Sound adjustments. The final section lays out a fault-finding guide to the most common faults.

When faced with a faulty computer, thereided of diagnosing the problem can seem a daunting task. With information of what should be correct in the system, inexpensive and easy-to-use tools, and a guide to the steps to take makes the task seem less daunting. When common sense is used and a logical approach taken, then there is a high probability of finding the fault on the computer.

The tools used with this guide are a logic probe and an inexpensive multimeter. The logic probe used to compile the information in this guide is an Altai (model HYT-07). Any reasonable multimeter can be used for the voltage readings.

#### USE OF THE LOGIC PROSE

The type of probe used has two leads. The black (-) lead is connected to a convenient "ground" such as the modulator case. The red (+) lead is connected to a +5 volts, d.c. supply. A handy place for this is the bottom of L2 (located below and right of the modulator). The metal probe on the main body of the logic probe is then placed on the item to be tested.

THE PULSE SWITCH ON THE PROBE IS PRESSED, IN FOR ALL TESTS

The results of the test are interpreted: where there is a "high" signal expected a "high" signal should be seen on the probe. There could be activity, or not, on some signals of the probe to that listed in the guide. (This is especially true if a different type of logic probe is used to that used to compile the guide.)

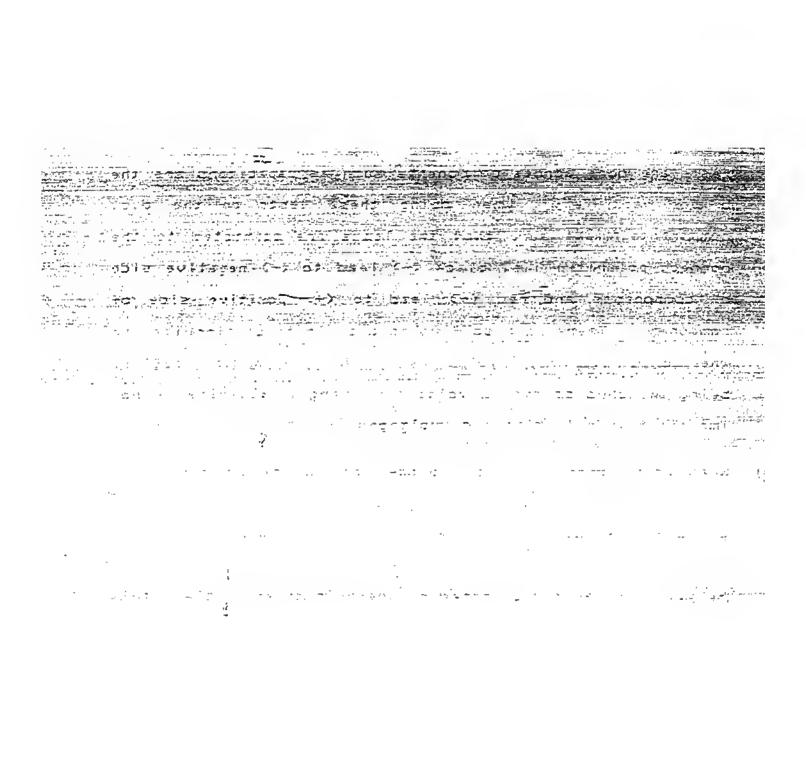

The important point is that essentially the results expected are either "high" (5 volts) or "low" (0 volts) and anything opposite to this is incorrect. The pulse element of any signal may not be present if the computer is "dead" as there will not be any activity going on. Signals very different from those listed in the guide should be treated as a suspect.

#### USE OF THE VOLTMETER (MULTIMETER)

A multimeter, set to the 12 volt d.c. voltage range, can be used instead of the logic probe for most tests. Readings in the clock circuits will not be reliable however. The black (-) lead is connected to the "grounds." The red (+) lead is placed on the item under test. Readings should follow those printed in the guide although an allowance of around can/-0.2 volts may be accepted, as the voltage readings in the guide are only to one decimal place. Again, results very different from those printed should be treated as suspect.

Only a voltmeter is suitable for checking the voltages in the Power Supply circuits. Most of the tests are done with the black (-) lead connected to a "ground." However, some bridge rectifier— When doing these tests on the diccomponents, make suce that the leads are connected to the correct polarity: i.e. black (-) lead to (-) megative side of components and red (+) glead to (+) positive side of component. There is also 9 volts a.c. in these circuits, so when checking the 9 volts a.c., the miltimeter requires being switched to the 12 volts a.c. range. Polarity is not important when testing a.c. voltages.

When using both the logic probe and the multimeter, care needs to be taken that adjacent pins on the I.C.s are not accidentally shorted together with the test probe. If this does occur, the computer may "crash." The computer needs to be switched off and switched on again in order to clear this: "crash."

#### 68000 CPU

The 68000 is an advanced 16-bit microprocessor. The CPU requires a single phase clock input at 8MHz. The chip operates on a single +5 volts supply.

The Amiga A500 utilizes three custom chips and a control chip. These are:

U3: FAT AGNUS - Custom Animation Chip. (or 8372A Fatter Agnus Chip)

U4: 8364 PAULA - Sound and Peripherals Chip

U5: 5719 GARY - Custom Control Chip

The Kickstart ROM (U6) contains the kernal and DOS routines

The two CIA chips 8520 (U7 & U8) provide the I/O interfacing

The external PSU provides outputs as follows:

· · Pin 1: +5 volts

Pin 2: Shield (GROUND)

Pin 3: +12 volts Pin 4: GROUND

Pin 5: -12 volts

#### NOTES

Pin numbers that have an asterisk with their label name are signals that are switched on and are active when the signal is in a "low" state.

Pin numbers without an asterisk to their label name are signals that are active in a 7 high " state.

Signals R0 to R3, G0 to G3 and B0 to B3 are connected to U40 and U41 respectively and are part of the color, and video functions.

Signals MiH, MOH and MOV, MIV are connected to U15 and are part of the Joystick Port functions.

#### NOTES

Pin numbers that have an asterisk with their label name are signals that are switched on and are active when the signal is in a "low" state.

Pin numbers without an asterisk to their label name are signals that are active in a "high " state.

Control Signals associated with U5 GARY are on pins :

2,3,4,10,11,12,13,14,15,18,19,20,21,22,23,25,26,27,28,29,30,-31,32,33,34,35,36,37,38,39,41,42 & 43

Floppy Functions associated with U5 GARY are on pins :

5,7,8,9,16,44,45,46 & 47

+5 Volts is supplied to the chip on gins :

5,17 & 48

The following pins are connected to Ground :

1,24 & 40

#### NOTES

Pin numbers that have an asterisk with their label name are signals that are switched on and are active when the signal is in a "low" state.

Pin numbers without an asterisk to their label name are signals that are active in a "high " state.

Signals FOTOX, POTOY, are inputs to the LEFT Joystick Control Fort (CN1).

Signals POTIX, POTIY, are inputs to the RIGHT Joystick Control Port (CN2)

Signals \*OKHD, DKHE, are connected to US GARY and are part of the Floppy Functions.

Signal \*DKRD is connected to the External Floppy Port (CNS)

Signals \*TXD, \*RXD, are connected to U38 and U39 respectively and are part of the RS232 Functions.

Signals AUD B (RIGHT), AUD A (LEFT) are connected to U14 and are part of the Audio Out Functions.
